

Analysis of Exclusive Processes

Andrew Pilkington

Presented at the Hera-LHC Working Group, Hamburg 06/04.

Overview

Two new analysis ideas:

- An exclusive Monte Carlo.
 - To decide whether exclusive higgs can be seen at the LHC
- A new exclusive jet definition.
 - New processes need new ideas

The EXHUME Monte Carlo

Written with James Monk (also Manchester). EXHUME implements the KMR model.

What can EXHUME do?

- Now:
 - Produce the Higgs at parton level.
 - Decay to $b\bar{b}$ and hadronise (using Pythia).
- Soon:
 - Produce $b\bar{b}$ and gg background.
- A bit after that:
 - Produce the bbg background
 - Allow other decays - not just $b\bar{b}$
- And finally:
 - Hadronise via Herwig (just for fun).

Current Output

(a) multiplicity

(b) Invariant mass of final state particles

(c) Rapidity of the higgs particle

(d) Transverse momentum of the b quark

Jet Definitions

Why?

- Analysis of Exclusive Higgs and Backgrounds at the LHC
- Exclusive dijet analysis
 - At the LHC for the exclusive higgs analysis, but also
 - At HERA and the Tevatron too?

How?

- Current Jet Finding done mainly by cones but also by clustering algorithms

Jets by Cones

- Cone defined in rapidity/phi space
$$\Delta R^2 = \Delta\phi^2 + \Delta\eta^2$$
- R defines a spatial extent of the jets.
- Certain amount of cone overlap allowed.

Distribution of Particles within 15 - 20GeV jets

(e)

(f)

Clusters by KTJet

- All particles, k , and all pairs of particles, kl , are given resolution variables

$$d_{kB} = 2E_k^2 (1 - \cos \theta_{kB})$$

$$d_{kl} = 2\min(E_k^2, E_l^2) (1 - \cos \theta_{kl})$$

- the d_{kB} are scaled by a factor R^2 .
- Particles are merged into jets by:
 - minimum resolution, d_{min} , found.
 - if d_{min} is a d_{kl} then these two objects are merged.
 - if d_{min} is a d_{kB} then the object k is defined to be a jet and removed from the list.

Defining Exclusive Jets

- Cone or Cluster.....
 - both have radius like R parameters to define jet extent.
 - both find jets but some particles left out ('out of cone radius').
- Exclusive events defined as (CDF):
 - 2 highest Et jets have a mass 0.8 of the missing mass (from roman pots).

A new Jet Definition for Exclusive Events

- Run KTJet algorithm in e^+e^- mode
 - tagged protons mean all particles belong in the analysis.
- Define
 - a stopping parameter $y_{cut} = \frac{Q_0^2}{E^2}$
 - the particle pair resolution $y_{kl} = \frac{d_{kl}}{E^2}$
- Objects merged until the minimum value of y_{kl} is larger than y_{cut}
- All remaining objects declared as jets.

The Analysis

- Exclusive Events generated with EXHUME.
- Double Pomeron Events generated with POMWIG
- What we want: y_{cut} at the onset of 2 jets (y_{32})

The Results

Value of Q_0 in merging 3 to 2 jets

for my 'inclusive background'

(g) exclusive

(h) Inclusive $b\bar{b}$

Figure 1: Number of jets found with a resolution of $Q_0 = 10$.

So it works - How well?

- Does it work better than the other method of defining exclusive events?

Possibly....

- Defining exclusive events this way keeps $\approx 100\%$ of the signal

But

- The inclusive background is larger than that found by the cone method.
- Cone algorithm also performing well on unsmeared data.

However

- When smearing occurs the advantage will be with the new jet definition.
- More on this very soon.....

Summary

- KMR-type exclusive events will soon be available in Monte Carlo format
- Jet Definitions are important in exclusive analysis.
