## C2GT

# Intercepting CERN neutrinos to Gran Sasso <br> in the Gulf of Taranto to measure $\boldsymbol{\theta}_{13}$ 

Presented by F. Dydak (CERN)

Figure 1: The deep-sea trench in the Gulf of Taranto

## Measuring $\sin ^{2} \theta_{13}$

Planetary neutrino oscillations are well described by

$$
\begin{aligned}
& P\left(\nu_{\mu} \rightarrow \nu_{\mathrm{e}}\right) \cong \sin ^{2} \theta_{23} \sin ^{2} 2 \theta_{13} \sin ^{2}\left(\frac{1.27 \Delta m_{23}^{2} L}{E_{\nu}}\right), \\
& P\left(\nu_{\mathrm{e}} \rightarrow \nu_{\tau}\right) \cong \cos ^{2} \theta_{23} \sin ^{2} 2 \theta_{13} \sin ^{2}\left(\frac{1.27 \Delta m_{23}^{2} L}{E_{\nu}}\right), \\
& P\left(\nu_{\mu} \rightarrow \nu_{\tau}\right) \cong \cos ^{4} \theta_{13} \sin ^{2} 2 \theta_{23} \sin ^{2}\left(\frac{1.27 \Delta m_{23}^{2} L}{E_{\nu}}\right) .
\end{aligned}
$$

For measuring $\sin ^{2} \theta_{13}$ : select $\nu_{\mu} \rightarrow \nu_{\mathrm{e}}$
For the transition $\nu_{\mu} \leftrightarrow \nu_{\mathrm{e}}$ at the maximum of the oscillation, the oscillation probability is:

$$
P\left(\nu_{\mathrm{e}} \rightarrow \nu_{\mu}\right) \cong 2 \sin ^{2} \theta_{13} .
$$

Needs a monoenergetic low-energy $\nu_{\mu}$ beam

- to permit a detector location at the maximal oscillation amplitude within a realistic distance
- to permit the suppression of NC-induced background

## Off-axis geometry

The longitudinal and transverse momenta of the $\nu_{\mu}$ in the laboratory system are

$$
\begin{aligned}
& p_{\mathrm{L}}=\gamma\left(p^{*} \cos \Theta^{*}+\beta p^{*}\right) \\
& p_{\mathrm{T}}=p^{*} \sin \Theta^{*},
\end{aligned}
$$

$p^{*}=0.03 \mathrm{GeV} / c=$ neutrino momentum
$\Theta^{*}=$ polar angle of neutrino emission w.r.t. the $\pi$ direction of flight. For $\Theta^{*}=90^{\circ}$ :

$$
\Theta=\frac{1}{\gamma} .
$$

Neutrino flux:

$$
\Phi_{\nu}(R)=\frac{\frac{\gamma^{2}}{\pi L^{2}}}{\left(1+\left(\gamma \frac{R}{L}\right)^{2}\right)^{2}},
$$

All-important feature:

$$
\frac{\partial E_{\nu}}{\partial \gamma}=0 .
$$

Figure 2: Neutrino energy from $\pi$ decay as a function of $\gamma_{\pi}$ at an off-axis angle $\theta=1 / 27.1$.

## Off-axis neutrinos in the Gulf of Taranto

Table 1: Parameters of neutrino beam and detector for a distance of 1200 km from CERN.

| Distance $L$ from CERN $[\mathrm{km}]$ | 1200 |
| :--- | :---: |
| Geodesic longitude | $017^{\circ} 54^{\prime} \mathrm{E}$ |
| Geodesic latitude | $39^{\circ} 47^{\prime} \mathrm{N}$ |
| Radial distance $R$ from CNGS beam axis $[\mathrm{km}]$ | 44 |
| $\gamma$ of parent pion | 27.1 |
| Parent-pion momentum $[\mathrm{GeV} / c]$ | 3.8 |
| Neutrino flux per decaying pion $\left[\mathrm{cm}^{-2}\right]$ | $4.1 \times 10^{-15}$ |
| Neutrino energy from pion decay $[\mathrm{GeV}]$ | 0.81 |
| Neutrino energy from Kaon decay $[\mathrm{GeV}]$ | 3.4 |

Figure 3: Oscillation pattern (top), neutrino flux bottom)

## Schematics of the deep-sea detector

Figure 4: Detector plane (top); $10 \mathrm{~m} \times 10 \mathrm{~m}$ Mechanical Module (bottom)

## Optical module

- efficient light detection in the wavelength range $300-550 \mathrm{~nm}$;
- maximal surface and angular acceptance;
- sensitivity to a single photoelectron;
- timing resolution $\leq 2$ ns;
- dark count probability $\leq 0.1$ photoelectron within a time window of 100 ns ;
- operation in sea water at a depth of $\sim 1000 \mathrm{~m}$.

Figure 5: Schematic view of the Optical Module (left), 3D schematic of the Optical Module (right).

## Pion production in target

Figure 6: Yield of $\pi^{ \pm}$from rotationally symmetric graphite targets with different absorption lengths and radii.
$3.3 \pi^{+}$per proton with momenta between 2 and $8 \mathrm{GeV} / c$ and polar angle $\leq 200 \mathrm{mrad}$ are used to estimate the neutrino flux.

With 'ideal' horn focussing, out of the initial $3.3 \pi^{+}$per proton, 1.5 can be bent parallel to the horn axis.

## Photon emission by electrons and muons of 800 MeV

Figure 7: Distance of emission of Cherenkov photons from the vertex, for 800 MeV electrons (top) and muons (bottom)

Table 2: Statistics of Cherenkov photons from 800 MeV electrons and muons

|  | electron | muon |
| :--- | :---: | :---: |
| generated | 138000 | 104000 |
| after absorption and scattering | 37500 | 33300 |
| photoelectrons | 610 | 530 |

## Electron and muon events of 800 MeV energy

Figure 8: Cherenkov rings of a typical electron (top) and muon (bottom) event with 800 MeV total energy; the vertex is located 20 m upstream of the detector plane

## Time distribution, vertex and energy reconstruction

Figure 9: Time distribution of the arrival of photons from 800 MeV electrons and muons from a vertex located 20 m from the detector plane (left); reconstructed longitudinal vertex coordinate (right)

Figure 10: Energy resolution of 800 MeV electrons and muons.

## Amplitude separation between electrons and muons

Figure 11: Average relative energy in the i.th non-zero cell when cells are ordered according to their energy content, for 800 MeV electrons (light) and muons (dark)

Figure 12: Separation of 800 MeV electrons and muons vs reconstructed longitudinal vertex position (left); purity versus efficiency of electrons w.r.t. muons (right); separation based on amplitude information only

## Characteristics of CC quasielastic events

Figure 13: Cosine of the polar angle of muons from the quasielastic reaction in the ${ }^{16} \mathrm{O}$ nucleus, versus muon momentum; process generated with program NEUGEN

Figure 14: Neutrino energy reconstructed from events with a single muon under the hypothesis of quasieleastic neutrino-nucleon scattering.

## Signal efficiencies and backgrounds

Table 3: Signal efficiencies after cuts

|  | CC quasielastic $\nu_{\mathrm{e}}$ | CC quasielastic $\nu_{\mu}$ |
| :--- | :---: | :---: |
| Removal of low-energy neutrinos | 0.8 | 0.8 |
| Removal of large-angle scattering | 0.9 | 0.9 |
| CC quasielastic $\nu_{\mu}$ suppression | 0.9 | - |
| NC $\pi^{0}$ suppression | 0.9 | - |
| Overall | 0.6 | 0.7 |

Table 4: Background percentages of unoscillated CC quasielastic $\nu_{\mu}$ events

|  | CC quasielastic $\nu_{\mathrm{e}}$ | CC quasielastic $\nu_{\mu}$ |
| :--- | :---: | :---: |
| $\nu_{\mathrm{e}}$ from $\mathrm{K}_{\mathrm{e} 3}$ and $\mu$ decays | $(0.2 \pm 0.1) \%$ | - |
| Misidentified CC quasielastic $\nu_{\mu}$ events | $(0.1 \pm 0.05) \%$ | - |
| $\pi^{0}$ from NC production | $(0.1 \pm 0.05) \%$ | - |
| $\pi^{ \pm}$from resonant NC production | - | $0.1 \%$ |
| Sum of backgrounds | $(0.4 \pm 0.1) \%$ | $0.1 \%$ |

## Oscillation parameters $\sin ^{2} \theta_{23}$ and $\Delta m_{23}^{2}$

Figure 15: Fit of the CC quasielastic $\nu_{\mu}$ rates at three different baselines in terms of $\sin ^{2} \theta_{23}$ and $\Delta m_{23}^{2}$; two points correspond to one year of data taking each, the point near the minimum uses the full statistics from five years of data taking.

Table 5: Precision of $\sin 2 \theta_{23}$ and $\Delta m_{23}^{2}$.

| error on $\sin ^{2} \theta_{23}$ | $\sim 8 \%$ |
| :--- | :--- |
| error on $\Delta m_{23}^{2}$ | $\sim 1 \%$ |

Table 6: Summary of C2GT parameters and expected results from five years of running at the 2 nd $\nu_{\mu}$ oscillation maximum in search of $\nu_{\mu} \rightarrow \nu_{\mathrm{e}}$ transitions; comparison with competing projects

|  | C2GT | T2K | $\mathrm{NO} \nu \mathrm{A}$ | Double-CHOOZ |
| :---: | :---: | :---: | :---: | :---: |
| Radius of instrumented detector disc [m] | 150 |  |  |  |
| Height of cone of fiducial volume [m] | 30 |  |  |  |
| Fiducial mass [Mt] | 1.5 |  |  |  |
| No. of $400 \mathrm{GeV} / c$ protons per year on target | $5 \times 10^{19}$ |  |  |  |
| No. of useful $\pi^{+}$decays per proton on target | 0.5 |  |  |  |
| Years of running at oscillation maximum | 5 |  |  |  |
| No. of $\nu_{\mu}$ CC interactions (unoscillated) | 3388 |  |  |  |
| No. of $\nu_{\mu}$ CC quasielastic interactions (unoscillated) | 2181 |  |  |  |
| CC quasielastic $\nu_{\mu}$ selection efficiency | 0.7 |  |  |  |
| No. of CC quasieleastic $\nu_{\mu}$ events after cuts (unoscillated) | 1527 |  |  |  |
| No. of background events for the $\nu_{\mathrm{e}}$ signal | 8.7 |  |  |  |
| Systematic error on background events | 30\% |  |  |  |
| CC quasielastic $\nu_{\mathrm{e}}$ selection efficiency | 0.6 |  |  |  |
| Discovery potential (3 ) on $\nu_{\mu} \rightarrow \nu_{\text {e }}$ probability | 0.0077 | 0.0060 |  |  |
| Discovery potential ( $3 \sigma$ ) on $\sin ^{2} \theta_{13}$ | 0.0039 |  |  |  |
| Discovery potential $(3 \sigma)$ on $\sin ^{2} 2 \theta_{13}$ | 0.0154 |  |  |  |
| Upper limit ( $90 \% \mathrm{CL}$ ) on $\nu_{\mu} \rightarrow \nu_{\mathrm{e}}$ probability | 0.0033 |  |  |  |
| Upper limit ( $90 \% \mathrm{CL}$ ) on $\sin ^{2} \theta_{13}$ | 0.0016 |  |  | 0.0125 |
| Same, including theoretical uncertainties |  | 0.0015 | $0.0011-0.0021$ |  |
| Upper limit ( $90 \% \mathrm{CL}$ ) on $\sin ^{2} 2 \theta_{13}$ | 0.0066 |  |  |  |
| No. of $\nu_{\mathrm{e}}$ observed signal events for $\sin ^{2} \theta_{13}=0.05$ | 131 |  |  |  |

## Educated guesses of Schedule and Cost

Schedule

- 2 years for R\&D, Design, Collaboration building, approval process
- 3 years for construction proper
- 1 year for installation and commissioning

Cost [MCHF]

| 32000 Optical Modules incl. electronics, cables | 75 |
| :--- | :---: |
| Mechanical Modules incl. superstructures | 35 |
| Sea operations | 40 |
| Total | 150 |

## R \& D programme

1. construction and testing of an HPD; this programme has been started already with the design and fabrication, at CERN, of prototypes with a smaller diameter; the smaller than final diameter ( 210 mm rather than the envisaged 380 mm ) is imposed by the use of existing equipment;
2. on-site measurements of sea water properties in 1000 m depth:

- velocity of water currents
- light absorption and scattering
- sedimentation
- residual background from daylight
- bioluminescence
- ${ }^{40} \mathrm{~K}$ background.

# C2GT: intercepting CERN neutrinos to Gran Sasso in the Gulf of Taranto to measure $\theta_{13}$ 

A.E. Ball, A. Braem, L. Camilleri, A. Catinaccio, G. Chelkov, F. Dydak, A. Elagin, P. Frandsen, A. Grant, M. Gostkin, A. Guskov, C. Joram, Z. Krumshteyn, H. Postema, M. Price, T. Rovelli, D. Schinzel, J. Séguinot, G. Valenti, R. Voss, J. Wotschack, A. Zhemchugov

#### Abstract

Today's most challenging issue in accelerator-based neutrino physics is to measure the mixing angle $\theta_{13}$ which is known to be much smaller than the solar $\theta_{12}$ and the atmospheric $\theta_{23}$. Yet establishing a finite value of $\theta_{13}$ is a prerequisite for observing CP violation in the neutrino mixing matrix. A deep-sea Cherenkov experiment with 1.5 Mt mass which utilizes the modified CNGS beam in off-axis geometry, is proposed in the Gulf of Taranto. The dominant beam component consists of monochromatic muonneutrinos of 800 MeV energy. The favourable profile of the seabed allows for a moveable experiment at three different baselines around 1200 km . The experiment will observe the oscillatory pattern of muon-neutrinos with full amplitude, will measure $\theta_{23}$ and especially $\Delta m_{23}^{2}$ with high precision, and will be sensitive to $\sin ^{2} \theta_{13}$ as small as 0.0016 ( $90 \%$ CL; theoretical uncertainties excluded).
