# Introduction to Web Services

#### **Objectives**

- Architecture
- Standards
  - XML Schema
  - SOAP
  - WSDL
  - UDDI
- Context for Web Services

#### **Section**

## INTRODUCTION

#### The concept of web services

- Web services is a messaging system which allows communication between objects.
- Messages can be synchronous or asynchronous.
- This system is loosely coupled (ie. Services should not be dependent on each other).

#### W3C view of Web Services

- The World Wide Web is more and more used for application to application communication.
- The programmatic interfaces made available are referred to as Web services.
- http://www.w3.org/2002/ws/

#### **Web Services**

- Web services are
  - Applications that enable remote procedure calls over a network or the Internet often using XML and HTTP
- Benefits
  - This allows us to hide the details of how a service is implemented;
     only URL and data types are required
  - It is largely irrelevant to the client whether the service is developed with Java or ASP.NET or if it is running on Windows, Linux or any other platform

#### W3C Web Services glossary

http://www.w3.org/TR/2004/NOTE-ws-gloss-20040211/

#### **Section**

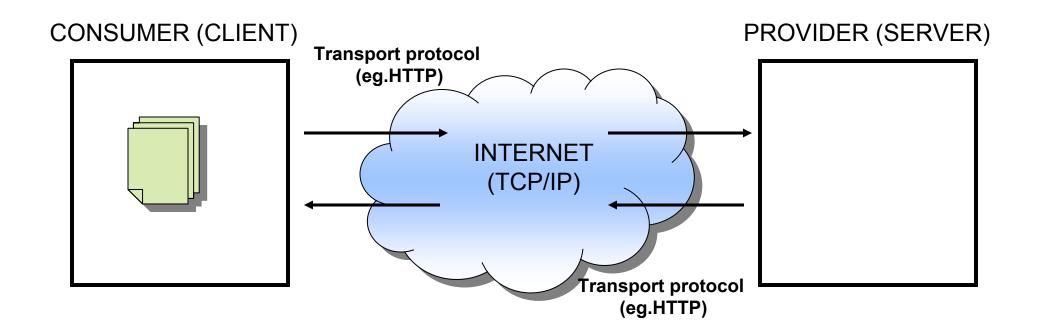

## Architecture

#### Web services architecture overview

#### Consumer (1)

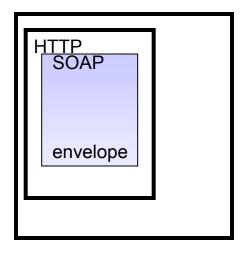

#### Web services architecture overview

#### Consumer (2)

**CONSUMER (CLIENT)** 

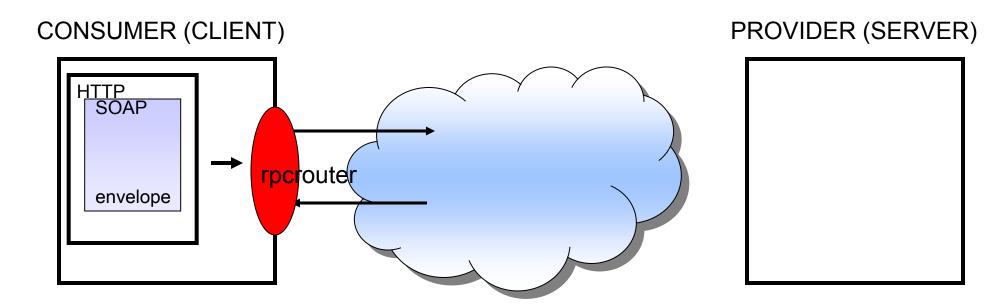

PROVIDER (SERVER)

#### Web services architecture overview

#### Consumer (3)

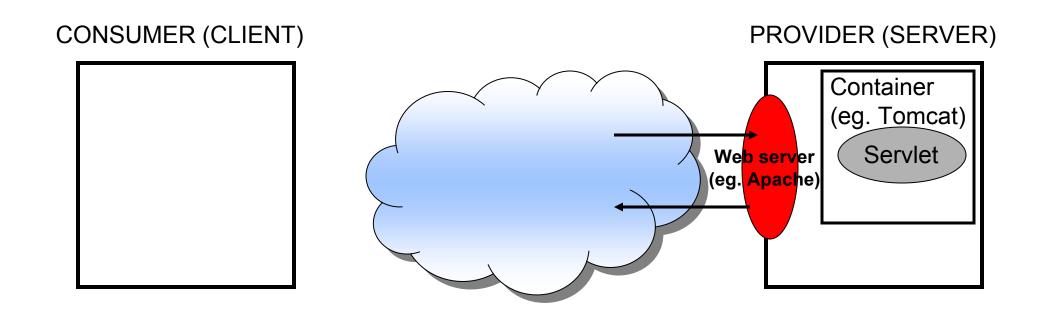

# Web services architecture overview Provider (1)

# CONSUMER (CLIENT) PROVIDER (SERVER) Container (eg. Tomcat) Servlet

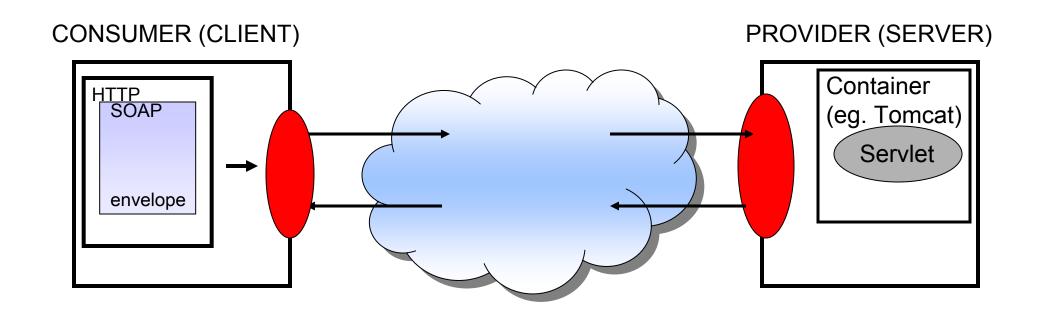

## Web services architecture overview Provider (2)

# Web services architecture overview Message transport (1)

#### Web services stack

Application	<b>4</b> ·····	Application (servlet)
rpcrouter		Web server
SOAP		SOAP
HTTP		HTTP
TCP/IP		TCP/IP
Infrastructure (Data link)		Infrastructure (Data link)

#### **Business mail analogy**

- The SOAP envelope is analogous to a business letter with an address within a distant organisation. This gives the information needed to get it from the sender's building to the recipient's building.
- The transport protocol is analogous to the carrier used for transport between buildings. (eg. FedEx.)
- The web server and container act like the local services for the recipient which place the message in his/her pigeonhole.

#### **Section**

### **Protocols**

#### **Communication and standards**

- Efficient (or indeed any) communication is dependent on a shared vocabulary and grammar.
- Because web services deals with inter-organisation communication these must be universal standards.

#### **Underlying standards**

- The basic standards for web services are:
- XML (Extensible Markup Language)
- SOAP (simple object access protocol)
- WSDL (web services description language)
- UDDI (universal description, discovery and integration)

#### The state of standards

- XML 1.0 fairly stable, although Schema are in the process of replacing DTDs (currently Schema 1.1 being worked on).
- SOAP 1.2
- WSDL 2.0 (coming out, 1.2 current)
- UDDI version 3 (Aug 2003)
- BPEL 1.1 (Business Process Execution Language)
- choreography description language (web services work flows) started January 2003.

Standards are still volatile and in the process of development.

#### **Web Services Architecture**

- Web Services involve three major roles
  - Service Provider
  - Service Registry
  - Service Consumer
- Three major operations surround web services
  - Publishing making a service available
  - Finding locating web services
  - Binding using web services

#### Making a service available (1)

- In order for someone to use your service they have to know about it.
- To allow users to discover a service it is published to a registry (UDDI).
- To allow users to interact with a service you must publish a description of it's interface (methods & arguments).
- This is done using WSDL.

#### Making a service available (2)

- Once you have published a description of your service you must have a host set up to serve it.
- A web server is often used to deliver services (although custom application – application communication is also possible).
- This is functionality which has to be added to the web server. In the case of the apache web server a 'container' application (Tomcat) can be used to make the application (servlet) available to apache (deploying).

# The old transfer protocols are still there.

- Like the grid architecture web services is layered on top of existing, mature transfer protocols.
- HTTP, SMTP are still used over TCP/IP to pass the messages.
- Web services, like grids, can be seen as a functionality enhancement to the existing technologies.

#### **XML**

- All Web Services documents are written in XML
- XML Schema are used to define the elements used in Web Services communication

#### SOAP

- Actually used to communicate with the Web Service
- Both the request and the response are SOAP messages
- The body of the message (whose grammar is defined by the WSDL) is contained within a SOAP "envelope"
- "Binds" the client to the web service

#### **WSDL**

- Describes the Web Service and defines the functions that are exposed in the Web Service
- Defines the XML grammar to be used in the messages
  - Uses the W3C Schema language

#### **UDDI**

- UDDI is used to register and look up services with a central registry
- Service Providers can publish information about their business and the services that they offer
- Service consumers can look up services that are available by
  - Business
  - Service category
  - Specific service

#### **Section**

## **XML**

#### What is XML

- XML stands for extensible markup language
- It is a hierarchical data description language
- It is a sub set of SGML a general document markup language designed for the American millitary.
- It is defined by w3c.

#### **How does XML differ from HTML?**

- HTML is a presentation markup language provides no information about content.
- There is only one standard definition of all of the tags used in HTML.
- XML can define both presentation style and give information about content.
- XML relies on custom documents defining the meaning of tags.

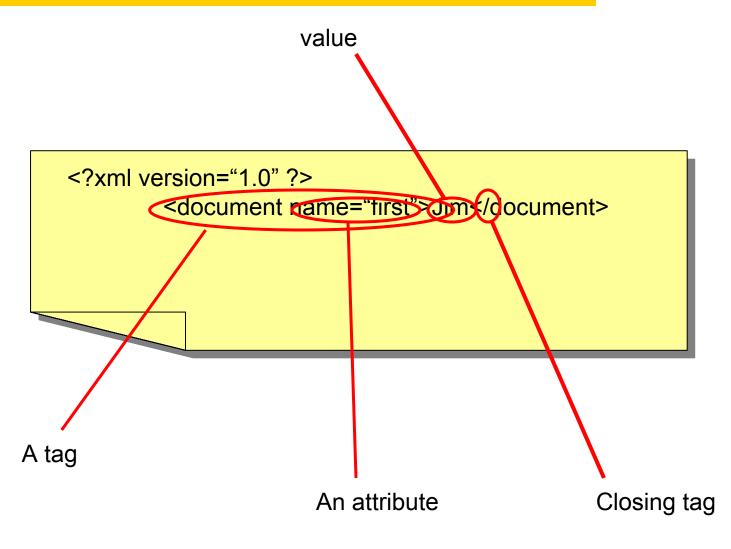

#### What is a Schema?

- A schema is the definition of the meaning of each of the tags within a XML document.
- Analogy: A HTML style sheet can be seen as a limited schema which only specifies the presentational style of HTML which refers to it.
- Example: in HTML the tag <strong> pre-defined. In XML you would need to define this in the context of your document.

#### A minimal XML document

#### Valid and well formed

- A correct XML document must be both valid and well formed.
- Well formed means that the syntax must be correct and all tags must close correctly (eg <...> </...>).
- Valid means that the document must conform to some XML definition (a DTD or Schema).

(Otherwise there can be no definition of what the tags mean)

#### Using namespaces in XML

 To fully qualify a namespace in XML write the namespace:tag name. eg.

```
<my_namespace:tag> </my_namespace:tag>
```

- In a globally declared single namespace the qualifier may be omitted.
- More than one namespace:

```
<my_namespace:tag> </my_namespace:tag>
<your_namespace:tag> </your_namespace:tag>
can co-exist if correctly qualified.
```

#### Namespaces in programming languages

- In C/C++ defined by #includes and classes (eg. myclass::variable).
- In PERL defined by package namespace, \$local and \$my (eg. myPackage::variable).
- In JAVA defined by includes and package namespace (eg. java.lang.Object)
- Defines the scope of variables

#### **Schema**

Simple schema saved as order.xsd

XML document derived from schema.

#### **Section**

## SOAP

## Request Response Web Services

- Currently the most common implementation of Web Services
- Work in a very simple 'request response' paradigm
- For Example:
  - A Weather Service
     simple request for weather in an area, simple response with
    the weather report
  - An Airline special offers service travel agents would simply make requests for latest offers and would receive the offers as a response

#### **SOAP** messages

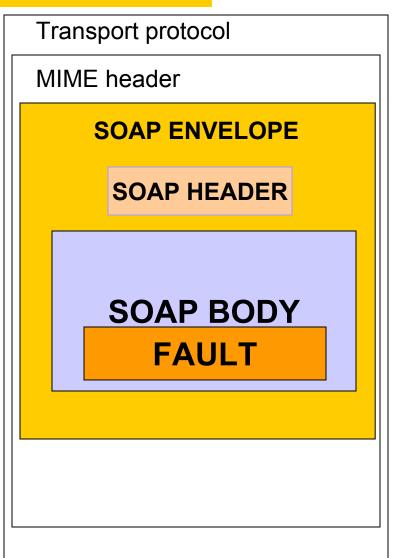

- SOAP provides a standard 'envelope' within which a message can be delivered.
- SOAP is mechanism (protocol) for transferring information (messages) between applications which may be widely distributed.
- SOAP says nothing about the content of the message the sender and the receiver must understand the message for themselves.
- SOAP is part of a communication stack.

## **SOAP Structure(1)**

- Each SOAP message will have:
  - An Envelope
  - A Header (optional)
  - A Body
  - The Body may contain a Fault element

## **SOAP Structure(2)**

- The envelope wraps the entire soap document
- The header contains allows additional information to be passed as well as the body of the document – e.g. authentication
- The body element contains the core of the SOAP document

   this will contain either the RPC call or the XML message itself
- The fault information will contain any exception information

## Anatomy of a SOAP message

```
<?xml version='1.0' encoding='UTF-8'?>
<SOAP-ENV: Envelope xmlns: SOAP ENV="http://schemas.xmlsoap.org/soap/envelope/"
        xmlns:xsi="http://www.w3c.org/1999/XMLSchema-instance"
        xmlns:xsd="http://www.w3c.org/1999/XMLSchema">
        <SOAP-ENV:Header>
        </SOAP-ENV:Header
        <SOAP ENV:Body>
        </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

## **SOAP** protocol binding

#### **SOAP RPC**

- SOAP RPC messages contain XML that represents a method call or method response
- The SOAP XML will be converted into a method call on the server and the response will be encoded into SOAP XML to be returned to the client

#### **SOAP Faults**

- SOAP errors are handled using a specialised envelope known as a Fault Envelope
- A SOAP Fault is a special element which must appear as an immediate child of the body element
- <faultcode> and <faultstring> are required.

#### A SOAP fault

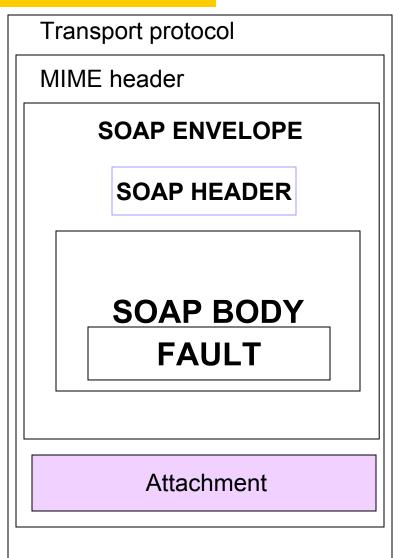

```
<?xml version='1.0' encoding='UTF-8'?>
<SOAP-ENV: Envelope xmlns: SOAP ENV="http://schemas.xmlsoap.org/soap/envelope/"
   xmlns:xsi="http://www.w3c.org/1999/XMLSchema-instance"
   xmlns:xsd="http://www.w3c.org/1999/XMLSchema">
   <SOAP ENV:Body>
             <SOAP-ENV:Fault>
                      <faultcode>SOAP-ENV:Server</faultcode>
                      <faultstring>Test fault</faultstring>
                      <faultactor>/soap/servlet/rpcrouter</faultactor>
                      <detail>
                      </detail>
             </SOAP-ENV:Fault>
   </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

#### **SOAP Attachment**

- Large quantities or binary data may not fit well into a XML SOAP message.
- In which case it can be sent 'out of band' by attaching it to a SOAP message
- Analogy : email attachments.

#### Attaching a file to a SOAP message

 To add a file to a SOAP message a tag is added within the body of the message.

<attachment href="{URL}"/>

</SOAP-ENV:Body>

#### **Section**

# **SOAP Deployment**

# Deployment: Making the container aware of a servlet

- The web server has to be aware of the interface and exposed methods of a servlet in order to use it.
- Using Tomcat as an example this can be done in a number of ways.

- 1. Enter the values manually into the SOAP admin page from a Deployment descriptor.
- 2. You can use the SOAP manager application from the command line
- 3. You can manually edit Tomcat's WEB-INFO/web.xml file
- 4. You can create a WAR file and place it in Tomcat's webapps folder
- 5. You can use ANT

## Using a WAR file

- A WAR file is basically an archive description of a servlet installation
  - (JAR and WAR naming derives from UNIX TAR java archive, web archive, tape archive).
- Example: placed in Tomcat's webapps folder it can be interpreted by the container.

## **Deployment Descriptor**

#### A SOAP manager file

Some containers (Tomcat) provide GUIs for deployment

#### **SOAP Implementations**

- There are several implementations of the SOAP Specification
  - Apache Axis
  - GLUE
- Most J2EE application servers contain a SOAP implementation
- .NET has a SOAP implementation
- SOAP is also implemented in PERL.

#### **Section**

# WSDL

#### The function of WSDL

- WSDL describes a service's exposed interface
- It is what a client sees of your service
- WSDL includes information about
  - The data types it uses
  - Parameters it requires and returns
  - Groupings of functionality
  - The protocol to be used to access the service
  - The location or address of the service

#### **WSDL Structure**

#### A WSDL document is an XML document

```
<?xml version="1.0" encoding="UTF-8"?>
<definitions>
   <types>
         <!- define the types here using XML Schema >
   </types>
   <message>
         <!- XML messages the web service uses are defined here \rightarrow
   </message>
   <portType>
         <!- define the input and output parameters here \rightarrow
   </portType>
   <br/>binding>
         <!- define the network protocol here →
   </binding>
   <service>
         <!- location of the service \rightarrow
   </service>
</definitions>
```

#### <import> element

#### <definitions

```
targetNamespace="urn:3950"

xmlns= "http://schema.xmlsoap.org/wsdl/"

xmlns:xsd= "http://www.w3c.org/2001/XMLSchema"

xmlns:soap= "http://schemas.xmlsoap.org/wsdl/soap/"

xmlnssoapenc= "http://schemas.xmlsoap.org/soap/emcoding/"

xmlns:tns= "urn:3950">
```

<import namespace= "http://nesc.ac.uk" location= "http://nesc.ac.uk/ez.xsd"/>

Acts like C/C++ #include, or Java import. Incorporates external namespaces

#### **Namespaces**

- WSDL uses a number of different namespaces including
- XML Schema Namespaces
  - http://www.w3.org/2000/10/XMLSchema
  - http://www.w3c.org/2001/XML-Schema-instance
- WSDL Namespaces
  - http://schemas.xmlsoap.org/wsdl/soap/
  - http://schemas.xmlsoap.org/wsdl/
- SOAP Namespaces
  - http://schemas.xmlsoap.org/soap/encoding
  - http://schemas.xmlsoap.org/soap/envelope

#### The <types>

 The types element contains XML Schemas defining the datatypes that are to be passed to and from the web service

#### The <message>

- The <message> element is used to define the messages that will be exchanged between the client and the service
- These message elements contain <part> elements, which will be using types defined in the types element

All the parts are namespace qualified

#### The <portType>

- The types and messages have been defined, but they have not been defined in terms of where they fit in the functionality of the web service
- This is done within <portType> and <operation> elements

- A portType is analogous to a class
- An operation is analogous to a method in that class

## Types of <operation>

- There are four distinct types of operation
- Synchronous
  - Request-response The service receives a message and sends a reply
  - Solicit-response The service sends a message and receives a reply message
- Asynchronous
  - One-way The service receives a message
  - Notification The service sends a message
- All of these can be defined in WSDL

## Defining the type of operation

- Presence and order of input/output elements defines the type of operation.
- Request-response < input > < output >
- Solicit-response <output><input>
- One-way <input> only
- Notification <output> only

## The <binding> element

- This element is used to define the mechanism that the client will actually use to interact with the web service
- There are three possibilities
  - 1. SOAP
  - HTTP
  - 3. MIME
- The most common choice is currently SOAP
- The binding element defines the protocol specific information for the portTypes previously defined

## The binding tag

```
<br/>
<binding name="ez3950SOAPBinding" type="tns:ez3950PortTypes">
```

The <binding> tag indicates that we will map a <Port Type> to a protocol

```
<soap:binding style="rpc"

transport="http://schemas.xmlsoap.org/soap/http/">
```

Indicates we will be using the SOAP binding extensions to map the operations. The alternative to "rpc" is "document".

```
( to use GET/POST use < http://dinding...>
to use MIME use < mime: binding....>)
```

## <br/> <br/> ding> Example

Below is an example of a binding element for SOAP

#### <service>

- The final component of a WSDL file is the <service>
  element
- The <service> element defines <port> elements that specify where requests should be sent

- The <soap:address> subelement identifies the URL of the service
- The precise content of <port> elements will be dependent upon the mechanism, i.e. SOAP, HTTP or MIME

## **Objectives**

- Architecture
- Standards
  - XML Schema
  - SOAP
  - WSDL
  - UDDI
- Context for Web Services
