Security Requirements

 Confidentiality Ensures that only authorised parties access the information. Authentication Ensures the originator of a message can provide appropriate proof of identity. Integrity Ensures that a message isn't modified accidentally or intentionally in transit. Nonrepudiation Guarantees that neither sender or receiver of a message can deny its transmission. Authorization Ensures that entities with given identity are given access to resources. 	 The Web services security roadmap laid out by IBM and Microsoft is composed of a whole suite of specifications covering various facets of security (messaging, policies, trust, privacy, etc.). The specifications build upon one another and are all built on top of a single specification, WS-Security, that defines a message security model. Currently the model for securing Web services consists of 7 specifications.

WS-Security Roadmap	WS-ReliableMessaging
WS-Secure Conversation WS-Federation WS-Authorisation Federation WS-Policy WS-Trust WS-Privacy Policy WS-Security Messaging XML Messaging Foundation (SOAP) Foundation	Motivating the Solution Some problems The current implementation of Web Services lacks guarantees of • Message Ordering • Once and only once delivery • Network/Machine availability The solution! A standard (therefore interoperable way) that would take care of all the above problems at the middleware layer. IBM, Microsoft, TIBCO and BEA are working together to develop a SOAP extension model to help solve these types of problems, and the result is WS-ReliableMessaging.

WS-Security

WS-RM Processing Model

- **()** A client application sends a new message to the SOAP client.
- The SOAP client, using WS-RM code, associates a unique identifier for this message and saves it in a persistent store.
- The WS-RM client tries to send the message to the target server. If it fails it retries until it times-out.
- Opon receiving the message, the WS-RM server code acknowledges receipt by sending an acknowledgment header.
- S After receiving the acknowledgment, the WS-RM client removes the message and the state information from the persistent store.
- **•** The SOAP server locates and invokes the desired Web Service.
- Once the service is invoked, the message can be sagely removed from the WS-RM sever-side runtime persistent store.
- In After the Expiration time has passed, the WS-RM server runtime can remove the state information about the particular message sequence.

WS-Coordination Introducing transactions to Web Services

Definition

A transaction is the scope under which a unit of work is defined. The size or breadth of the amount of work will vary between applications.

- Intuitively, the above definitions means considering several successive calls as a single atomic one.
- This is particularly useful for Banking applications or Business systems where several subsystems need to be updated and either all or none of the updates succeed.

Concluding Remarks	
5	
In this lecture we saw	
 A programmatic interface to the UDDI Registry using IBM's open source UDDI4J 	
 The Web Services Security Roadmap (WS-Security) 	
 Current work in transactions and reliable messaging 	
 Finally, future uses on the Grid 	
Thank you!
