

Service Availability Monitoring

eGee
Enabling Grids
for E-science

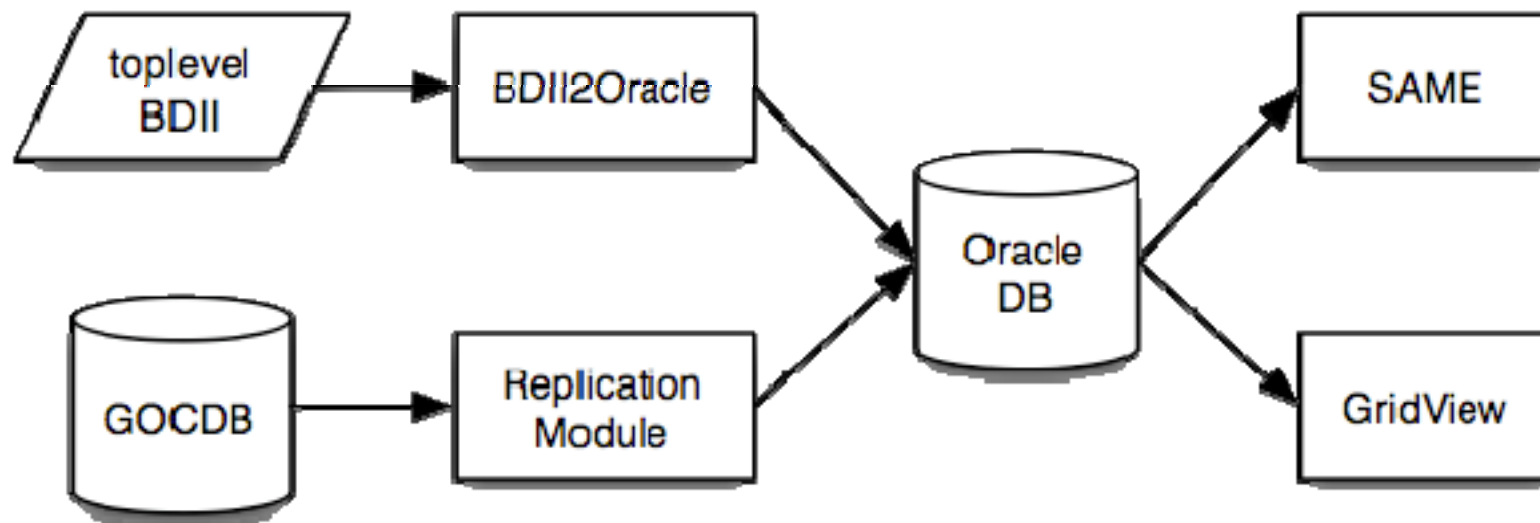

Piotr Nyczyk, CERN IT/GD

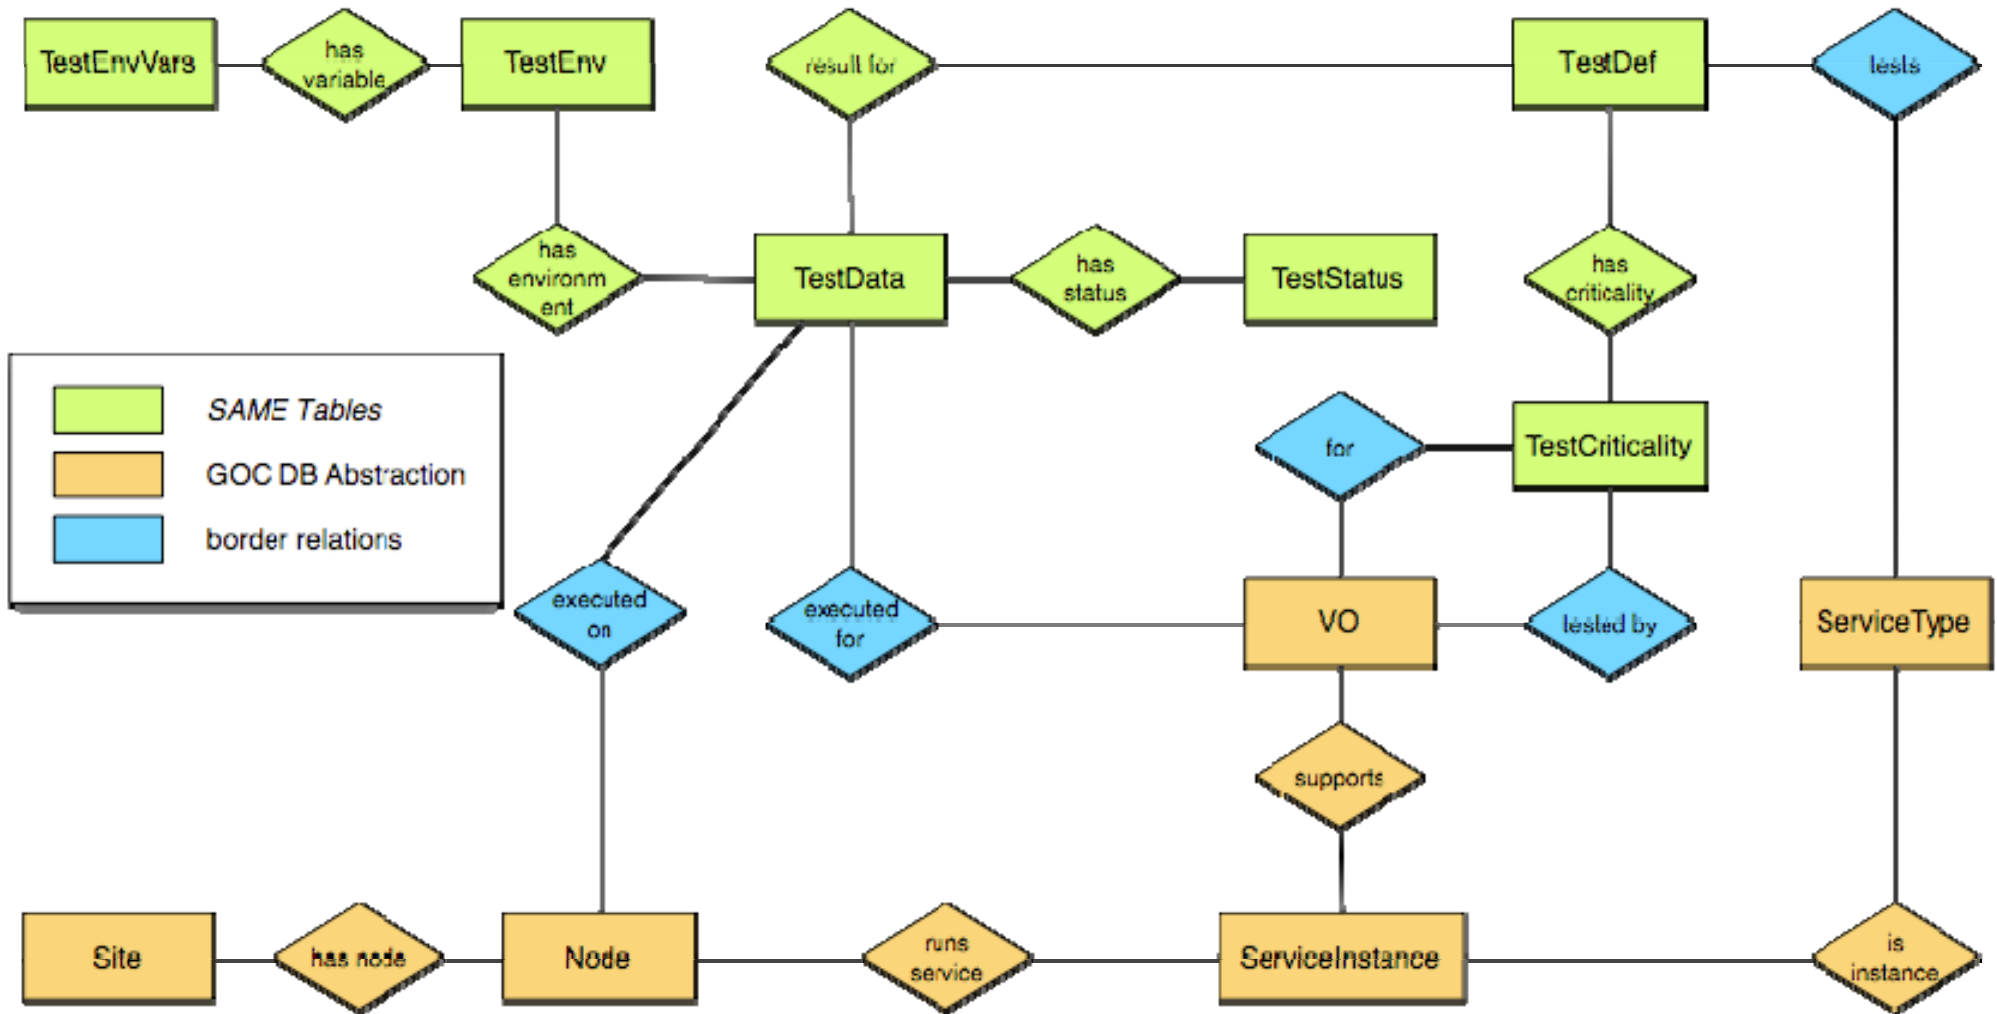

Krakow, May 17th, 2006

- In monitoring: need to compare “what is there?” with “what should be there?”
- GOC DB is used for “what should be there?” factor:
 - information about sites (name, GIIS URL, status, type)
 - service instances (site and central services)
- GOC DB is not used directly - read only replica in GridView Oracle DB
- BDII is used to complement GOCDB information

- Additional tables in GridView replica of GOCDDB filled in intelligently by replication script:
 - Site-Organization relation
 - Site-Tier relation
- Redesigned schema in SAME DB replacing part of GOCDDB dealing with service instances and nodes
- Abstraction layer implemented over the rest of GOC DB using views and additional GridView tables
- Missing information gathered and merged into DB from BDII (supported VOs, discovery of nodes)

- CE - currently SFT, in future SAME framework
- RB - Dave Kant's standalone sensor
- site-BDII - GStat
- toplevel-BDII - GStat
- FTS - simple sensor in SAME Framework
 - full n-to-n channels test needed and to be done
